Any general theory of biomineralization must explain the formation of solid phases from biological fluids in terms of physical parameters such as supersaturation, ionic strength, pH, surface energies and the character and quantity of active sites.

This skeletal tissue called stereom [3,12] forms intracellularly or extracellularly and is usually perforated by a network of mesh-like cavities. Morphologically, echinoderm ossicles form an endoskeleton, produced by mesenchymal cells and are usually covered by epidermis [4].

Our understanding of the evolutionary pattern of mineralizing metazoans is intimately linked to the comprehension of the way in which metazoans acquired the capacity to construct mineralized body part. The genes and molecular mechanisms that control biomineralization processes are gradually being identified (2, 3). In addition to their mineral moieties, metazoan skeletons—in particular those constructed from calcium carbonate—contain an organic extracellular matrix.

The biomineralization 7 processes use aqueous solutions at temperatures below 100 C and no toxic intermediates are produced in these systems. From a serious global en- ronmental problem point of view, the development of processes inspired by biomineralization would offer valuable insights into material science and en- neering to reduce energy ...

In deuterostomes, the phosphatic vertebrate skeleton and the calcitic echinoderm skeleton (intercalated by the soft-bodied cephalochordates, tunicates and hemichordates) share cellular and molecular processes in their early skeletogenesis, yet the protein-coding genes essential to downstream biomineralization processes were acquired largely ...

For example, captive crocodylians exposed to constant temperature, diet, and photoperiod, still exhibit the periodic and cyclical skeletal growth banding of their wild counterparts. Consequently, it is assumed by many paleontologists that the growth lines of dinosaurs reflect annual rhythms, and that they may be used to determine individual ages.

Age determination in dinosaurs - Wikipedia

It encompasses the formation of largely inorganic minerals by the processes of life. Examples of biomineralization are the formation of calcium phosphate to create bones for structure, calcium carbonate as protective shells, iron oxide to store iron in animal cells, and the formation of magnetite as orientational materials in magnetobacterial cells (Table III).

Age determination in dinosaurs is mainly used to determine the approximate age of a dinosaur when the creature died. Contents[show] History Early attempts to estimate the longevity of dinosaurs used allometric scaling principles. Ages were determined by dividing individual mass estimates by rates of growth for similar, extant taxa. For very large individuals, growth rates were extrapolated to ...
